HARVARD MEDICAL SCHOOL

Introduction

Background

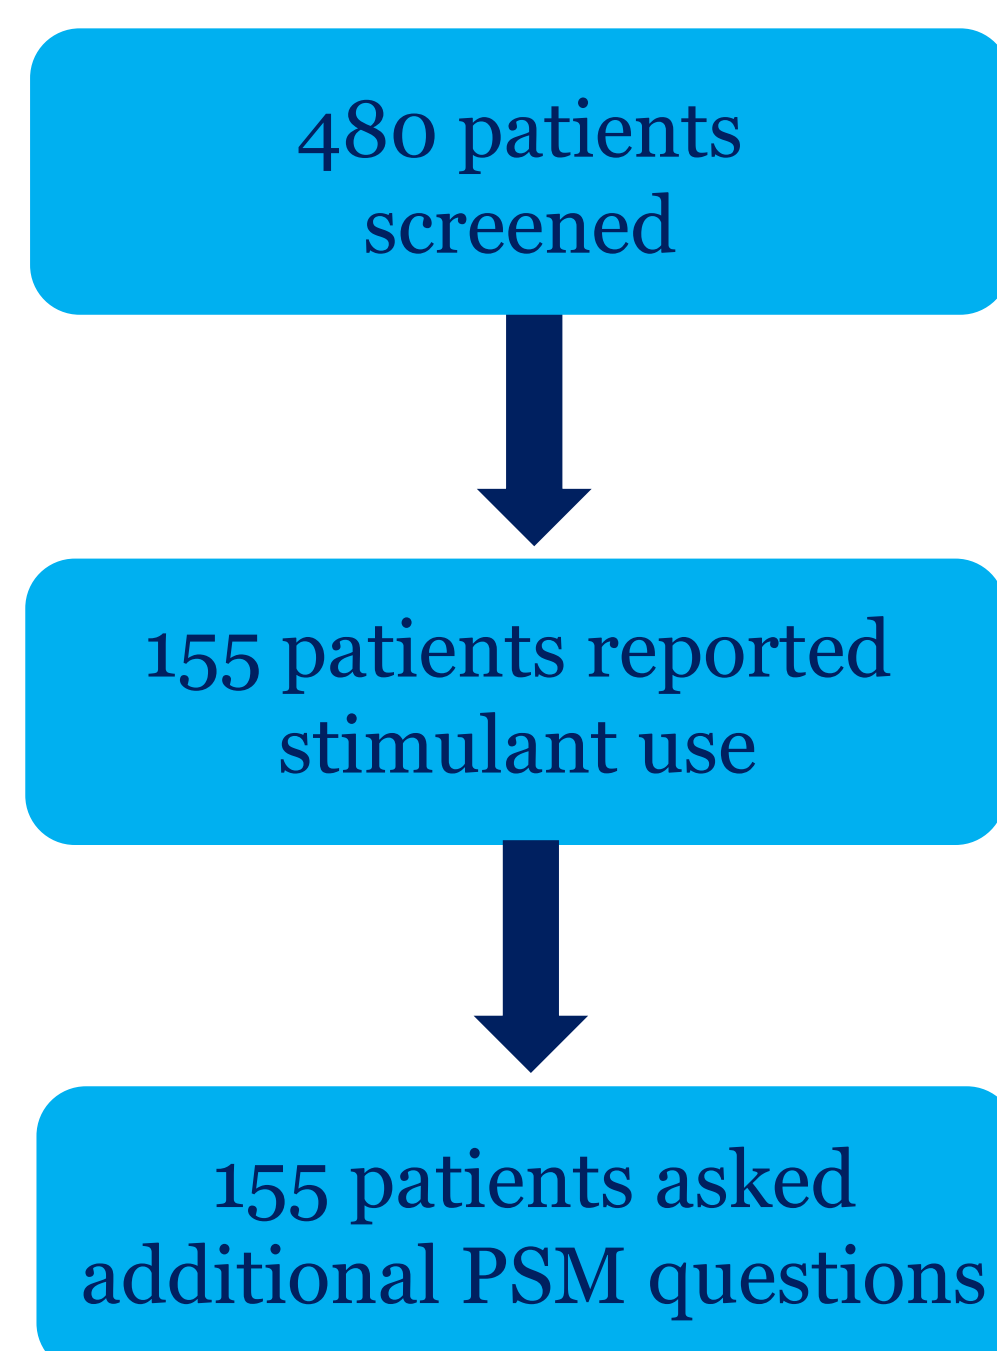

- Stimulant use, particularly prescription stimulant misuse (PSM) is understudied among service members and veterans.
 - PSM is mainly studied within academic environments.
 - Substance use screening tools used with military personnel primarily assess alcohol and cannabis use.
 - Assessments of stimulant use often neglect to screen for *prescription* stimulant use, misuse, and attitudes.

Aims

- Examine the prevalence and characteristics of stimulant use/PSM in a military (veteran and service member) patient sample.
- Assess perceived attitudes and knowledge of PSM.

Method

- Participants (N=480) completed a substance use screening questionnaire before initiating care at an outpatient mental health clinic.
- Past two-week substance use of: alcohol, cannabis, stimulant (prescribed or non-prescribed), opiate, and steroid use was assessed:
 - Participants that endorsed stimulant use were asked additional questions about PSM, as well as their perceptions, attitudes, and knowledge of PSM.

Results

Prevalence

- 155 participants (33%)** reported *any* form of **stimulant use** (e.g. cocaine, Adderall, methamphetamines, etc.) in the past two weeks.
- New patients who identified as Black were more likely to endorse recent prescribed or non-prescribed stimulant use (54%) than were new patients who identified as White (28%; $p < .05$).
- New patients who were employed were more likely than those who were unemployed to report stimulant use ($p < .05$).

Stimulant use is prevalent within this treatment-seeking, military sample with a third of new patients endorsing past two-week use. Perceptions, attitudes, and knowledge of prescription stimulant misuse within this group highlight areas for improved screening and clinical intervention.

Results

Attitudes, Perceptions, and Knowledge

“I am aware of the recommended dosage levels for prescription stimulant use”

“The healthcare Providers that I have been to have talked to me about the safety of prescription stimulants”

“Misusing prescription stimulants occasionally is harmless”

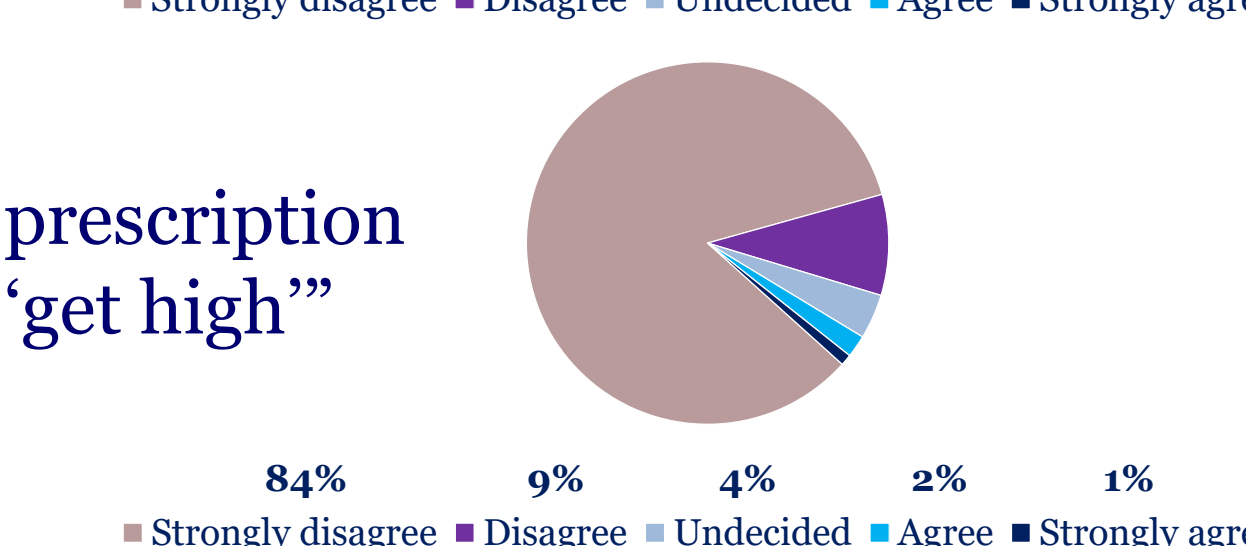

“I have taken prescription stimulants to help me socialize better”

“I have taken prescription stimulants to help me lose weight”

“I have taken prescription stimulants to ‘get high’”

Discussion

Takeaways

- Stimulant use is prevalent within this treatment-seeking, military sample.
 - Clinics serving this demographic should ensure assessment of stimulant use and PSM.
- Stimulant use might be more common among certain demographic groups.
 - Treatment team should consider factors contributing to these differences.
- PSM was only endorsed by 1% of patients when directly provided with the PSM definition, yet based on responses to the attitudes, perceptions, and knowledge questionnaire many more patients *endorsed engaging in forms of PSM*.
 - Clinical assessments should be as destigmatizing as possible, with questions about specific PSM behaviors.
- Clinical screening and intervention informed by patient's attitudes, perceptions, and knowledge of PSM is crucial.

Future Directions

- An expansion of studies assessing stimulant use, particularly PSM, within military samples is warranted.
- Additional studies will be critical to inform clinical intervention following positive screens.
